

Files Profiler

Find what's unused, merge what's duplicated, and safely re-point references — across every asset type in your Unity project, from one editor window.

Installation

Option A — Unity Package Manager (local package)

1. Copy the `com.creatush.filesprofiler` folder anywhere outside `Assets/` (e.g. next to your project, or inside a `LocalPackages/` folder).
2. In Unity: **Window → Package Manager → "+" → Add package from disk...**
3. Select the `package.json` inside that folder.

Or add it directly to your `Packages/manifest.json` :

```
{
  "dependencies": {
    "com.creatush.filesprofiler": "file:../LocalPackages/com.creatush.filesprofiler"
  }
}
```

Option B — Drop into Assets/

If you'd rather not package it, just copy the `Editor/` folder's contents into:

```
Assets/
└─ Creatush/
   └─ FilesProfiler/
      └─ Editor/
         ├── AssetCategories.cs
         ├── FilesScanner.cs
         ├── FilesProfilerWindow.cs
         └─ Creatush.FilesProfiler.Editor.asmdef
```

Either way, Unity compiles it automatically — no extra setup, no third-party dependencies.

Opening the window

```
Unity menu bar → Tools → Files Profiler
```

Concepts

Categories

Every file in your project is bucketed into one of these on discovery, by extension:

Category	Extensions
Textures	<code>.png .jpg .jpeg .tga .psd .tiff .tif .bmp .exr .hdr .dds .gif .webp</code>
Audio	<code>.wav .mp3 .ogg .aiff .aif .flac .mod .it .s3m .xm</code>
Models	<code>.fbx .obj .blend .dae .3ds .dxf .c4d .max .ma .mb</code>
Materials	<code>.mat</code>
Prefabs	<code>.prefab</code>
Animation	<code>.anim .controller .overridecontroller .mask .playable .signal</code>
Shaders	<code>.shader .shadergraph .shadersubgraph .compute .cginc .hlsl .glsl</code>
Fonts	<code>.ttf .otf .fon .fnt</code>
Data Assets	<code>.asset .preset</code> (ScriptableObjects)
Scenes	<code>.unity</code>
Scripts	<code>.cs .js .boo</code>
Other	anything else (<code>.json .xml .txt .csv .pdf .md ...</code>)

A category dropdown at the top of the window lets you focus on one, or pick **All** to view everything combined.

Scan scope

Two buttons:

- ► **Scan "X"** — scans only the active category. Faster; ideal when you only care about one type of asset right now.
- ►► **Scan All** — scans every category in one pass.

Reference detection always checks the whole project's reference-bearing files (materials, prefabs, scenes, controllers, etc.) regardless of which button you press — only the list of things being *checked* narrows. Scanning just Audio still correctly finds an audio clip referenced from a prefab anywhere in scope.

Scans are additive per category: running "Scan All" and then re-scanning a single tab only refreshes that tab's data.

Unused panel

Lists every file with **zero references** anywhere in the reference-bearing files in scope.

- **Search** and, when viewing "All", a **Category** filter.
- Click any row to ping it in the Project window.
- Checkbox multi-select, with **Select All / Clear**.
- **Remove Selected (N)** — deletes the checked files (and their `.meta` sidecars) via `AssetDatabase.DeleteAsset`, after a confirmation dialog. The footer shows a live running total of the selected files' combined size.

Duplicates panel

Groups files that are either byte-for-byte identical (MD5) or share the same filename, scoped per category.

- The first file in each group is the default **KEEP** target; click **Make Keep** on any other row to promote it instead.
- A checkbox per non-kept row controls which duplicates are included in a merge (defaults to "everything except the kept file").
- **Merge Selected (N)** → redirects every checked duplicate's GUID to the kept file's GUID across all reference files, after showing a dry-run-backed confirmation with the real file/replacement counts.
- **Auto-remove duplicates after merge** — when enabled, the merged-away files are permanently deleted right after the GUID redirect completes. A warning banner appears whenever this is on.
- **Backup (.bak) before merge** — independent toggle, on by default.
- → **Swap tab** on any row sends just that one file to the GUID Swap tab for manual control instead of a group merge.

Example: an "exit button" icon got imported five times across different folders. Open Duplicates, find the group, leave the four extras checked (or adjust which one is "keep"), hit **Merge Selected (4)** →, confirm. Every material/prefab/scene that referenced any of the four duplicates now points at the one you kept — and if auto-remove was on, the four redundant files are gone too.

GUID Swap tab

The general-purpose version of the merge tool above — works on **any** two assets, not just detected duplicates.

- Drag any file (or a whole folder, recursively) from the Project window onto the drop zone to add it to the picker list.
- Each row has an inline **Role** dropdown: `None / From / To`. Setting a new `From` clears the previous one automatically (same for `To`).
- **Preview** shows every reference file that would change, without writing anything.
- Uncheck **Dry run**, then **Apply Swap** to commit. `.bak` backups are created unless disabled.

How it works internally

- **Discovery** — a single `AssetDatabase.FindAssets("")` pass over the chosen scope, bucketed into categories by extension. Every file lands in *some* category, even unknown types (via "Other").
- **Unused detection** — every reference-bearing file type is scanned via `AssetDatabase.GetDependencies()`. Pure binary leaf types (textures, audio, fonts) are skipped as *reference sources* for speed, since they never embed GUID text themselves — but they're still fully checked as *targets* for being referenced.
- **Duplicates** — MD5 of raw file bytes (exact) or filename match.
- **GUID Swap** — direct text replacement of the old GUID with the new one across every reference-bearing file. Works identically regardless of asset type, since Unity references everything by GUID the same way.

Notes & safety

- Editor-only — the `asmdef` restricts compilation to the Editor platform, so none of this ships in builds.
- No third-party packages required.
- Unity 2021.3 LTS or newer.
- Swap and Merge operations write files **outside** Unity's undo system. Keep `.bak` backups on until you're confident, and always run a dry run or preview first.
